

FEMA Disaster Analysis Project

This project is about understanding natural disasters in the United States using data analysis. The work is completed in four steps, where each step helps to understand disasters in a better way.

In the beginning, the dataset was collected and cleaned. Some values were missing or not in the correct format, so they were fixed. The date column was converted properly, and important fields like year and month were created. This step was very important because clean data gives correct results.

After cleaning, the next step was to analyse disasters over time. It was observed that the number of disasters has increased over the years. Some years had a sudden rise in disasters. Also, certain months showed more disasters, which means disasters follow seasonal patterns.

Then, geographical analysis was performed to understand where disasters happen the most. It was found that some states have more disasters than others. Coastal and southern states are more affected because they face storms, hurricanes, and floods. Different states also experience different types of disasters, showing that location plays an important role.

In the final step, disaster types were analysed. It was found that disasters like floods and storms occur most frequently. Some states repeatedly face the same type of disasters, which shows a clear pattern.

The analysis also included government assistance programs. It was observed that major disasters require more support. Public Assistance programs are used more often than Individual Assistance programs. In serious disasters, both types of assistance are provided.

By combining all these steps, we get a complete understanding of disasters. The analysis shows that disaster patterns depend on time, location, and type. Some areas are more vulnerable, and disasters are increasing over time.

Overall, this project helps in understanding disaster trends and patterns. These insights can help in better planning, disaster management, and resource allocation in the future.
